Introduction

1 Categorical prerequisites

In this section we try to make a brief account of the majority of the relevant prerequisites needed to discuss derived categories.

1.1 Additive, k -linear and abelian categories

We mainly follow [KS06].

A categorical *biproduct* of objects X and Y in a category \mathcal{C} is an object $X \oplus Y$ together with morphisms

$$\begin{array}{ll} p_X: X \oplus Y \rightarrow X & p_Y: X \oplus Y \rightarrow Y \\ i_X: X \rightarrow X \oplus Y & i_Y: Y \rightarrow X \oplus Y \end{array}$$

for which the pair p_X, p_Y is the categorical product of X and Y and the pair i_X, i_Y is the categorical coproduct. For a pair of morphisms $f_X: Z \rightarrow X$ and $f_Y: Z \rightarrow Y$ the unique induced morphism into the product $Z \rightarrow X \oplus Y$ is denoted by (f_X, f_Y) and for a pair of morphisms $g_X: X \rightarrow Z$ and $g_Y: Y \rightarrow Z$ the unique induced morphism from the coproduct $X \oplus Y \rightarrow Z$ is denoted by $\langle g_X, g_Y \rangle$. For morphisms $f_0: X_0 \rightarrow Y_0$ and $f_1: X_1 \rightarrow Y_1$ we introduce notation $f_0 \oplus f_1: X_0 \oplus X_1 \rightarrow Y_0 \oplus Y_1$ to mean either of the two (equal) morphisms

$$(\langle f_0, 0 \rangle, \langle 0, f_1 \rangle) \quad \text{or} \quad \langle (f_0, 0), (0, f_1) \rangle$$

also depicted in matrix notation as

$$\begin{pmatrix} f_0 & 0 \\ 0 & f_1 \end{pmatrix}.$$

Let k denote either a field or the ring of integers \mathbf{Z} .

Definition 1.1. A category \mathcal{A} is additive (resp. k -linear) if all the hom-sets carry the structure of abelian groups (resp. k -modules) and the following axioms are satisfied

Decide on which terminology to use (everything is covered by k -linear...)

A1 For all all objects X, Y and Z of \mathcal{A} the composition

$$\circ: \text{Hom}_{\mathcal{A}}(Y, Z) \times \text{Hom}_{\mathcal{A}}(X, Y) \rightarrow \text{Hom}_{\mathcal{A}}(X, Z)$$

is bilinear.

A2 There exists a *zero object* 0 , for which $\text{Hom}_{\mathcal{A}}(0, 0) = 0$.

A3 For any two objects X and Y there exists a categorical biproduct of X and Y .

Remark 1.2. (i) The zero object 0 of a k -linear category \mathcal{A} is both the initial and terminal object of \mathcal{A} .

(ii) One can recognize k -linear categories as the categories enriched over the category Mod_k of k -modules and k -linear maps.

Definition 1.3. A functor $F: \mathcal{A} \rightarrow \mathcal{A}'$ between two additive (resp. k -linear) categories \mathcal{A} and \mathcal{A}' is *additive* (resp. *k -linear*), if its action on morphisms

$$\text{Hom}_{\mathcal{A}}(X, Y) \rightarrow \text{Hom}_{\mathcal{A}'}(F(X), F(Y))$$

is a group homomorphism (resp. k -linear map).

Traditionally the term *additive* is reserved for \mathbf{Z} -linear categories and \mathbf{Z} -linear functors between such categories.

For a morphism $f: X \rightarrow Y$ in an additive category \mathcal{A} recall, that the *kernel* of f is the equalizer of f and 0 in \mathcal{A} , if it exists, and, dually, the *cokernel* of f is the coequalizer of f and 0 . It is well-known and easy to verify, that the structure maps $\ker f \hookrightarrow X$ and $Y \twoheadrightarrow \operatorname{coker} f$ are monomorphism and epimorphism respectively. We also define the *image* and the *coimage* of f to be

$$\begin{aligned} (\operatorname{im} f \rightarrow Y) &:= \ker(Y \rightarrow \operatorname{coker} f) \\ (X \rightarrow \operatorname{coim} f) &:= \operatorname{coker}(\ker f \rightarrow X). \end{aligned}$$

Notice that the image and the coimage, just like the kernel and the cokernel, are defined to be morphisms, not only objects. Sometimes these are called *structure morphisms*.

For a monomorphism $Y \hookrightarrow X$ we will sometimes by abuse of terminology call the cokernel $\operatorname{coker}(Y \rightarrow X)$ a *quotient* and denote it by X/Y .

Definition 1.4. A k -linear category \mathcal{A} is *abelian*, if it is closed under kernels and cokernels and satisfies axiom **A4**.

A4 For any morphism $f: X \rightarrow Y$ in \mathcal{A} the canonical morphism $\operatorname{coim} f \xrightarrow{\sim} \operatorname{im} f$ is an isomorphism.

$$\begin{array}{ccccc} \ker f & \hookrightarrow & X & \xrightarrow{f} & Y & \twoheadrightarrow & \operatorname{coker} f \\ & & \downarrow & & \uparrow & & \\ & & \operatorname{coim} f & \xrightarrow{\sim} & \operatorname{im} f & & \end{array}$$

Axiom **A4** essentially states that abelian categories are those additive categories possessing all kernels and cokernels in which the first isomorphism theorem holds.

Remark 1.5. We obtain the morphism mentioned in axiom **A4** in the following way. Due to $(\operatorname{im} f \rightarrow Y) = \ker(Y \rightarrow \operatorname{coker} f)$ and the composition $X \rightarrow Y \rightarrow \operatorname{coker} f$ being 0 , there is a unique morphism $X \rightarrow \operatorname{im} f$ by the universal property of kernels. The composition $\ker f \rightarrow X \rightarrow \operatorname{im} f$ then equals 0 , by $\operatorname{im} f \hookrightarrow Y$ being a monomorphism and $\ker f \rightarrow X \rightarrow Y$ equaling 0 . From the universal property of cokernels we then obtain a unique morphism $\operatorname{coim} f \rightarrow \operatorname{im} f$, because $(X \rightarrow \operatorname{coim} f) = \operatorname{coker}(\ker f \rightarrow X)$.

Example 1.6. The default examples of abelian categories are the category of abelian groups \mathbf{Ab} or more generally the category of A -modules \mathbf{Mod}_A for a commutative ring A and the categories of coherent and quasi-coherent sheaves $\mathbf{coh}(X)$ and $\mathbf{qcoh}(X)$ on a scheme X . On the other hand the category of (real or complex) vector bundles over a manifold of dimension at least 1 is additive, but never abelian. The last claim is due to the latter category not being closed under kernels and cokernels.

Definition 1.7. Let

$$X \xrightarrow{f} Y \xrightarrow{g} Z$$

be a sequence of composable morphisms in an abelian category \mathcal{A} .

- (i) We say this sequence is *exact*, if $g \circ f = 0$ and the induced morphism $\operatorname{im} g \rightarrow \ker f$ is an isomorphism.
- (ii) Extending (i), a sequence $\cdots \rightarrow X^0 \rightarrow X^1 \rightarrow X^2 \rightarrow \cdots$ is *exact*, if any subsequence $X^{i-1} \rightarrow X^i \rightarrow X^{i+1}$ for $i \in \mathbf{Z}$ is exact.

(iii) Exact sequences of the form $0 \rightarrow X \rightarrow Y \rightarrow Z \rightarrow 0$ are called *short exact sequences*.

To relate the definition of exactness with more primitive objects of an abelian category, namely kernels and cokernels, it is not difficult to show that

$$0 \rightarrow X \rightarrow Y \rightarrow Z \text{ is exact, if and only if } (X \rightarrow Y) = \ker(Y \rightarrow Z),$$

and dually

$$X \rightarrow Y \rightarrow Z \rightarrow 0 \text{ is exact, if and only if } (Y \rightarrow Z) = \operatorname{coker}(X \rightarrow Y).$$

In the context of abelian categories, functors, which preserve a bit more than just the k -linear structure, are of interest. This brings us to the notion of exactness of additive functors.

Definition 1.8. Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be an additive functor between abelian categories.

- (i) F is said to be *left exact*, if $0 \rightarrow FX \rightarrow FY \rightarrow FZ$ is exact for any short exact sequence $0 \rightarrow X \rightarrow Y \rightarrow Z \rightarrow 0$ in \mathcal{A} .
- (ii) F is said to be *right exact*, if $FX \rightarrow FY \rightarrow FZ \rightarrow 0$ is exact for any short exact sequence $0 \rightarrow X \rightarrow Y \rightarrow Z \rightarrow 0$ in \mathcal{A} .
- (iii) F is said to be *exact*, if it is both left and right exact.

Remark 1.9. Equivalently, one can also define left exact functors to be exactly those additive functors, which commute with kernels and dually define right exact functors to be additive functors commuting with cokernels.

1.2 Triangulated categories

In order to formulate the definition of a triangulated category more concisely, we introduce some preliminary notions. A *category with translation* is a pair (\mathcal{D}, T) , where \mathcal{D} is a category and T is an auto-equivalence $T: \mathcal{D} \rightarrow \mathcal{D}$ called the *translation functor*. If \mathcal{D} is additive or k -linear, T is moreover assumed to be additive or k -linear. We usually denote its action on objects X with $X[1]$ and likewise its action on morphisms f with $f[1]$.

A *triangle* in a category with translation (\mathcal{D}, T) is a triplet of composable morphisms (f, g, h) of category \mathcal{D} taking the form

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1].$$

A *morphism* of triangles $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$ and $X' \xrightarrow{f'} Y' \xrightarrow{g'} Z' \xrightarrow{h'} X'[1]$ is given by a triple of morphisms (u, v, w) , for which the diagram below commutes.

$$\begin{array}{ccccccc} X & \longrightarrow & Y & \longrightarrow & Z & \longrightarrow & X[1] \\ u \downarrow & & v \downarrow & & w \downarrow & & u[1] \downarrow \\ X' & \longrightarrow & Y' & \longrightarrow & Z' & \longrightarrow & X'[1] \end{array}$$

One can compose morphisms of triangles in the obvious way and the notion of an isomorphism of triangles is defined as usual. The following definition as stated is originally due to Verdier, who first introduced it in his thesis [Ver96].

Definition 1.10. A *triangulated category* (over k) is a k -linear category with translation (\mathcal{D}, T) equipped with a class of *distinguished triangles*, which is subject to the following four axioms.

- TR1** (i) Any triangle isomorphic to a distinguished triangle is also itself distinguished.
(ii) For any X the triangle

$$X \xrightarrow{\text{id}_X} X \longrightarrow 0 \longrightarrow X[1]$$

is distinguished.

- (iii) For any morphism $f: X \rightarrow Y$ there is a distinguished triangle of the form

$$X \xrightarrow{f} Y \longrightarrow Z \longrightarrow X[1].$$

The object Z is sometimes called the *cone of f* .

TR2 The triangle

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$$

is distinguished if and only if

$$Y \xrightarrow{g} Z \xrightarrow{h} X[1] \xrightarrow{-f[1]} Y[1]$$

is distinguished.

TR3 Given two distinguished triangles and morphisms $u: X \rightarrow X'$ and $v: Y \rightarrow Y'$, depicted in the solid diagram below

$$\begin{array}{ccccccc} X & \xrightarrow{f} & Y & \xrightarrow{g} & Z & \xrightarrow{h} & X[1] \\ u \downarrow & & v \downarrow & & w \downarrow & & u[1] \downarrow \\ X' & \xrightarrow{f'} & Y' & \xrightarrow{g'} & Z' & \xrightarrow{h'} & X'[1] \end{array}$$

satisfying $v \circ f = f' \circ u$, there exists a (in general non-unique) morphism $w: Z \rightarrow Z'$, for which (u, v, w) is a morphism of triangles i.e. the diagram above commutes.

TR4 ...

Omitting the so-called *octahedral* axiom TR4 we arrive at the definition of a *pre-triangulated category*. These are essentially the categories we will be working with, since we will never use nor verify the axiom TR4. We will nevertheless use the terminology “*triangulated category*” in part to remain consistent with the existent literature and more importantly because our categories will be honest triangulated categories anyways.

Remark 1.11. The object Z , called the *cone of f* , in axiom **TR1** (iii) is unique up to isomorphism. This is seen through the use of axiom **TR3** in combination with example 1.20 and the five lemma [KS06, Lemma 8.3.13] from homological algebra in Mod_k .

Proposition 1.12. Let $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$ be a distinguished triangle in a triangulated category \mathcal{D} . Then $g \circ f = 0$.

Proof. □

Definition 1.13. Let \mathcal{D} and \mathcal{D}' be triangulated categories with translation functors T and T' respectively. An additive functor $F: \mathcal{D} \rightarrow \mathcal{D}'$ is defined to be *triangulated* or *exact*, if the following two conditions are satisfied.

Maybe I will pick only triangulated, to not overload the term exact...

(i) There exists a natural isomorphism of functors

$$\eta: F \circ T \simeq T' \circ F.$$

(ii) For every distinguished triangle

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$$

in \mathcal{D} , the triangle

$$F(X) \xrightarrow{Ff} F(Y) \xrightarrow{Fg} F(Z) \rightarrow F(X)[1]$$

is distinguished in \mathcal{D}' , where the last morphism (of degree 1) is obtained as the composition $F(Z) \xrightarrow{Fh} F(X[1]) \xrightarrow{\eta_X} F(X)[1]$.

Remark 1.14. The condition on F being an *additive* functor in the above definition is actually unnecessary and follows from conditions (i) and (ii) [The25, Tag 05QY].

this remark may be omitted.

Definition 1.15. Let \mathcal{D}_0 and \mathcal{D} be triangulated categories such that \mathcal{D}_0 is a subcategory of \mathcal{D} . Then \mathcal{D}_0 is a *triangulated subcategory* of \mathcal{D} , if the inclusion functor $i: \mathcal{D}_0 \hookrightarrow \mathcal{D}$ is a triangulated functor.

Proposition 1.16. Let \mathcal{D} be a triangulated category and $\mathcal{D}_0 \subseteq \mathcal{D}$ a full additive subcategory of \mathcal{D} . Assume that the translation functor T of \mathcal{D} restricts to an autoequivalence T_0 of \mathcal{D}_0 and that for every distinguished triangle $X \xrightarrow{f} Y \rightarrow Z \rightarrow X[1]$ in \mathcal{D} , where f belongs to \mathcal{D}_0 , the object Z is isomorphic to some object of \mathcal{D}_0 . Then \mathcal{D}_0 is naturally equipped with a triangulated structure, for which it becomes a triangulated subcategory of \mathcal{D} .

Proof. We take T_0 to be the translation functor on \mathcal{D}_0 and take distinguished triangles in \mathcal{D}_0 to be all the triangles of \mathcal{D}_0 , for which there exists an isomorphism of triangles to some distinguished triangle of \mathcal{D} . Then \mathcal{D}_0 is clearly triangulated and the inclusion functor $i: \mathcal{D}_0 \hookrightarrow \mathcal{D}$ is triangulated. \square

Definition 1.17. Triangulated categories \mathcal{D} and \mathcal{D}' are said to be *equivalent* (as triangulated categories), if there are triangulated functors $F: \mathcal{D} \rightarrow \mathcal{D}'$ and $G: \mathcal{D}' \rightarrow \mathcal{D}$, such that $G \circ F \simeq \text{id}_{\mathcal{D}}$ and $F \circ G \simeq \text{id}_{\mathcal{D}'}$ and we call F and G *triangulated equivalences*.

Proposition 1.18. Let $F: \mathcal{D} \rightarrow \mathcal{D}'$ be a triangulated functor, which is an equivalence of categories with a quasi-inverse $G: \mathcal{D}' \rightarrow \mathcal{D}$. Then G is also a triangulated functor.

Proof. This is a consequence of [Huy06, Proposition 1.41], as equivalences of categories are special instances of adjunctions. \square

As a consequence, two triangulated categories are equivalent (as triangulated categories) whenever there exists a fully faithful essentially surjective triangulated functor from one to the other.

Definition 1.19. Let $H: \mathcal{D} \rightarrow \mathcal{A}$ be an additive functor from a triangulated category \mathcal{D} to an abelian category \mathcal{A} . We say H is a *cohomological functor*, if for every distinguished triangle $X \rightarrow Y \rightarrow Z \rightarrow X[1]$ in \mathcal{D} , the induced long sequence in \mathcal{A}

$$\cdots \rightarrow H(X) \rightarrow H(Y) \rightarrow H(Z) \rightarrow H(X[1]) \rightarrow H(Y[1]) \rightarrow H(Z[1]) \rightarrow \cdots \quad (1.1)$$

is exact.

Construction of the long sequence (1.1) is extremely simple as opposed to other known long exact sequences assigned to certain short exact sequences (e.g. of sheaves or complexes) as all the complexity is actually captured within the distinguished triangle already. All one has to do is unwrap the triangle $X \rightarrow Y \rightarrow Z \rightarrow X[1]$ into the following chain of composable morphisms

$$\cdots \rightarrow Y[-1] \rightarrow Z[-1] \rightarrow X \rightarrow Y \rightarrow Z \rightarrow X[1] \rightarrow Y[1] \rightarrow Z[1] \rightarrow X[2] \rightarrow \cdots$$

and apply functor H over it.

Example 1.20. For any object W in a triangulated category \mathcal{D} the functors

$$\mathrm{Hom}_{\mathcal{D}}(W, -): \mathcal{D} \rightarrow \mathbf{Mod}_k \text{ and } \mathrm{Hom}_{\mathcal{D}}(-, W): \mathcal{D}^{\mathrm{op}} \rightarrow \mathbf{Mod}_k$$

are cohomological¹. Let us verify the first claim. Consider the long exact sequence

$$\cdots \rightarrow \mathrm{Hom}_{\mathcal{D}}(W, X) \rightarrow \mathrm{Hom}_{\mathcal{D}}(W, Y) \rightarrow \mathrm{Hom}_{\mathcal{D}}(W, Z) \rightarrow \mathrm{Hom}_{\mathcal{D}}(W, X[1]) \rightarrow \cdots$$

arising from a distinguished triangle $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$. Since the translation functor on \mathcal{D} and the axiom TR2 allow us to turn this triangle and still end up with a distinguished triangle, it suffices to verify only that

$$\mathrm{Hom}_{\mathcal{D}}(W, X) \xrightarrow{f_*} \mathrm{Hom}_{\mathcal{D}}(W, Y) \xrightarrow{g_*} \mathrm{Hom}_{\mathcal{D}}(W, Z) \quad \text{is exact.}$$

By proposition 1.12 we see that $\mathrm{im} f_* \subseteq \ker g_*$, so we are left to prove the other inclusion. Suppose $v: W \rightarrow Y$ is in $\ker g_*$. Then axiom TR3 (together with TR2 and TR1 (ii)) asserts the existence of a morphism $u: W \rightarrow X$ making the diagram below commutative.

$$\begin{array}{ccccccc} W & \xrightarrow{\mathrm{id}_W} & W & \longrightarrow & 0 & \longrightarrow & W[1] \\ \downarrow u & & \downarrow v & & \downarrow w & & \downarrow u[1] \\ X & \xrightarrow{f} & Y & \xrightarrow{g} & Z & \xrightarrow{h} & X[1] \end{array}$$

As this is the first argument with the axioms of triangulated cats, I could maybe expand it a little bit more.

From the commutative square on the left it is then clear that $v \in \mathrm{im} f_*$, as $v = f \circ u$.

Proposition 1.21. Let $X \xrightarrow{f} Y \rightarrow Z \rightarrow X[1]$ be a distinguished triangle in a triangulated category \mathcal{D} . Then f is an isomorphism if and only if $Z \simeq 0$.

Proof. We argue with a chain of equivalences. Observe that f is an isomorphism if and only if $f_*: \mathrm{Hom}_{\mathcal{D}}(W, X) \rightarrow \mathrm{Hom}_{\mathcal{D}}(W, Y)$ and $f^*: \mathrm{Hom}_{\mathcal{D}}(Y, W) \rightarrow \mathrm{Hom}_{\mathcal{D}}(X, W)$ are isomorphisms for all objects W of \mathcal{D} . From the existence of long exact sequences established in the previous example the latter condition is equivalent to $\mathrm{Hom}_{\mathcal{D}}(W, Z) = 0$ and $\mathrm{Hom}_{\mathcal{D}}(Z, W) = 0$ for all W , which in turn is equivalent to $Z \simeq 0$. \square

The following are all specialized results characterizing, when a fully faithful triangulated functor is an equivalence. We will exploit corollary 1.25 and proposition 1.27 in the proof of the final theorem in section ??.

Definition 1.22. Let \mathcal{D} be a triangulated category and $\mathcal{D}_0, \mathcal{D}_1$ its triangulated subcategories. We say \mathcal{D} *decomposes* into \mathcal{D}_0 and \mathcal{D}_1 if the following three conditions are met.

¹With claiming that $\mathrm{Hom}_{\mathcal{D}}(-, W)$ is cohomological we are being slightly imprecise, as we have not clarified what the triangulated structure on $\mathcal{D}^{\mathrm{op}}$ is. We take it to be the most obvious one (cf. [Mil, Ch. 1, 1.2]).

- (i) Categories \mathcal{D}_0 and \mathcal{D}_1 contain objects not isomorphic to 0.
- (ii) Every object X of \mathcal{D} fits into a distinguished triangle (in \mathcal{D}) of the form

$$Y_0 \rightarrow X \rightarrow Y_1 \rightarrow Y_0[1],$$

where Y_0 and Y_1 belong to \mathcal{D}_0 and \mathcal{D}_1 respectively.

- (iii) For all objects Y_0 of \mathcal{D}_0 and Y_1 of \mathcal{D}_1 it holds that

$$\mathrm{Hom}_{\mathcal{D}}(Y_0, Y_1) = 0 \quad \text{and} \quad \mathrm{Hom}_{\mathcal{D}}(Y_1, Y_0) = 0.$$

Additionally, \mathcal{D} is called *indecomposable*, if it can not be decomposed in this way.

Lemma 1.23. *Let $F: \mathcal{D} \rightarrow \mathcal{D}'$ be a fully faithful triangulated functor between triangulated categories \mathcal{D} and \mathcal{D}' . Suppose F has a right adjoint $F \dashv H: \mathcal{D}' \rightarrow \mathcal{D}$. Then F is an equivalence if and only if for any object Z in \mathcal{D}' the condition $H(Z) \simeq 0$ implies $Z \simeq 0$.*

Proof. (\Rightarrow) Let Y belong to \mathcal{D}' . Since F is part of an equivalence, the counit $\varepsilon_Y: FH(Y) \rightarrow Y$ is also an isomorphism, thus, as $H(Y) \simeq 0$ implies $FH(Y) \simeq 0$, we see that $Y \simeq 0$.

(\Leftarrow) Recall, that whenever F is part of an adjunction $F \dashv H$, it is fully faithful if and only if the unit $\eta: \mathrm{id}_{\mathcal{D}} \Rightarrow HF$ is an isomorphism [The25, Tag 07RB]. Thus it suffices to show that the counit $\varepsilon: FH \Rightarrow \mathrm{id}_{\mathcal{D}'}$ is an isomorphism. Pick an object Y of \mathcal{D}' and extend $\varepsilon_Y: FH(Y) \rightarrow Y$ to a distinguished triangle $FH(Y) \rightarrow Y \rightarrow Z \rightarrow FH(Y)[1]$ in \mathcal{D}' . After applying the triangulated functor H (cf. [Huy06, Prop. 1.41]) to the latter triangle, we obtain

$$HFH(Y) \xrightarrow{H(\varepsilon_Y)} H(Y) \longrightarrow H(Z) \longrightarrow HFH(Y)[1].$$

By the triangle identity relating units and counits of an adjunction [The25, Tag 0GLL], we have

$$H(\varepsilon_Y) \circ \eta_{H(Y)} = \mathrm{id}_{H(Y)},$$

and as observed earlier, since $\eta_{H(Y)}$ is an isomorphism, $H(\varepsilon_Y)$ is as well. It follows by 1.21 that $H(Z) \simeq 0$, from which, by the assumption, $Z \simeq 0$ follows. Finally, by 1.21 again, ε_Y is an isomorphism, proving our claim. \square

Proposition 1.24. *Let $F: \mathcal{D} \rightarrow \mathcal{D}'$ be a fully faithful triangulated functor between triangulated categories \mathcal{D} and \mathcal{D}' having both left and right adjoints $G \dashv F \dashv H$. Further assume \mathcal{D} has objects not isomorphic to 0 and that \mathcal{D}' is indecomposable. Then F is an equivalence if and only if for all objects Y in \mathcal{D}' the condition $H(Y) \simeq 0$ implies $G(Y) \simeq 0$.*

Proof. \square

Corollary 1.25. *Let $F: \mathcal{D} \rightarrow \mathcal{D}'$ be a fully faithful triangulated functor between triangulated categories \mathcal{D} and \mathcal{D}' with $G: \mathcal{D}' \rightarrow \mathcal{D}$ simultaneously being its left and right adjoint $G \dashv F \dashv G$. Further assume \mathcal{D} has objects not isomorphic to 0 and that \mathcal{D}' is indecomposable. Then F is an equivalence.*

For the last part of this section let k denote a field.

Definition 1.26. Let \mathcal{D} be a triangulated category over k with $\mathrm{Hom}_{\mathcal{D}}(X, Y)$ being a finite dimensional k -vector space for all objects X and Y of \mathcal{D} . A *Serre functor* is a triangulated autoequivalence $S: \mathcal{D} \rightarrow \mathcal{D}$ of \mathcal{D} , such that for all objects X and Y there exists an isomorphism of k -vector spaces

$$\sigma_{X,Y}: \mathrm{Hom}_{\mathcal{D}}(X, Y) \xrightarrow{\sim} \mathrm{Hom}_{\mathcal{D}}(Y, S(X))^{\vee},$$

which is natural in both arguments X and Y , thus forming a natural isomorphism of functors $\mathcal{D}^{\mathrm{op}} \times \mathcal{D} \rightarrow \mathrm{Mod}_k$.

Proposition 1.27. Suppose $F: \mathcal{D} \rightarrow \mathcal{D}'$ is a triangulated functor of triangulated categories \mathcal{D} and \mathcal{D}' endowed with Serre functors $S_{\mathcal{D}}$ and $S_{\mathcal{D}'}$ respectively. Assume F has a left adjoint $G \dashv F$. Then $S_{\mathcal{D}} \circ G \circ S_{\mathcal{D}'}^{-1}$ is right adjoint to F .

Proof. For any two objects X of \mathcal{D} and Y of \mathcal{D}' we compute

$$\begin{aligned} \mathrm{Hom}_{\mathcal{D}'}(F(X), Y) &\simeq \mathrm{Hom}_{\mathcal{D}'}(Y, S_{\mathcal{D}'}(F(X)))^{\vee} \\ &\simeq \mathrm{Hom}_{\mathcal{D}'}(S_{\mathcal{D}'}^{-1}(Y), F(X))^{\vee} \\ &\simeq \mathrm{Hom}_{\mathcal{D}}(G(S_{\mathcal{D}'}^{-1}(Y)), X)^{\vee} \\ &\simeq \mathrm{Hom}_{\mathcal{D}}(X, S_{\mathcal{D}}(G(S_{\mathcal{D}'}^{-1}(Y))))^{\vee\vee} \\ &\simeq \mathrm{Hom}_{\mathcal{D}}(X, S_{\mathcal{D}}(G(S_{\mathcal{D}'}^{-1}(Y)))). \end{aligned}$$

For this is a chain of natural equivalences of functors in X and Y , it follows that

$$F \dashv S_{\mathcal{D}} \circ G \circ S_{\mathcal{D}'}^{-1}. \quad \square$$

1.3 Categories of complexes

In order to define derived categories of an additive category \mathcal{A} we first introduce the category of complexes and the homotopic category of complexes of \mathcal{A} . We will equip the latter with a triangulated structure. We also recall cohomology of chain complexes and introduce quasi-isomorphisms. Throughout this section \mathcal{A} will be a fixed additive or k -linear category and we also mention that we will be using the cohomological indexing convention.

As a preliminary we introduce the *graded objects* of \mathcal{A} to be \mathbf{Z} -indexed sequences $A^{\bullet} = (A^i)_{i \in \mathbf{Z}}$ of objects A^i of \mathcal{A} . A *morphism* $f: A^{\bullet} \rightarrow B^{\bullet}$ of degree $k \in \mathbf{Z}$ is a sequence $(f^i: A^i \rightarrow B^{i+k})_{i \in \mathbf{Z}}$ of morphisms of \mathcal{A} . Bundling up all this data, we obtain the \mathbf{Z} -graded category of \mathcal{A} denoted by $\mathcal{A}^{\mathbf{Z}}$, consisting of graded objects of \mathcal{A} and morphisms of all integer degrees. It can also be thought of as the functor category from the free category of \mathbf{Z} to \mathcal{A} , hence the notation $\mathcal{A}^{\mathbf{Z}}$.

Category of chain complexes

By a *chain complex* in \mathcal{A} we mean a collection of objects and morphisms

$$A^{\bullet} = \left((A^i)_{i \in \mathbf{Z}}, (d_A^i: A^i \rightarrow A^{i+1})_{i \in \mathbf{Z}} \right),$$

where A^i are objects and d^i are morphisms of \mathcal{A} , called *differentials*, subject to equations $d^{i+1} \circ d^i = 0$, for all $i \in \mathbf{Z}$. A complex is *bounded from below* (resp. *bounded from above*), if there exists $i_0 \in \mathbf{Z}$ for which $A^i \simeq 0$ for all $i \leq i_0$ (resp. $i \geq i_0$) and is *bounded*, if it is both bounded from below and bounded from above. A *chain map* between two chain complexes A^{\bullet} and B^{\bullet} in \mathcal{A} is a collection of morphisms in \mathcal{A}

$$f^{\bullet} = (f^i: A^i \rightarrow B^i)_{i \in \mathbf{Z}},$$

for which $f^{i+1} \circ d_A^i = d_B^i \circ f^i$ holds for all $i \in \mathbf{Z}$. This may diagrammatically be described by the following commutative ladder.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & A^{i-1} & \xrightarrow{d_A^{i-1}} & A^i & \xrightarrow{d_A^i} & A^{i+1} \longrightarrow \cdots \\ & & \downarrow f^{i-1} & & \downarrow f^i & & \downarrow f^{i+1} \\ \cdots & \longrightarrow & B^{i-1} & \xrightarrow{d_B^{i-1}} & B^i & \xrightarrow{d_B^i} & B^{i+1} \longrightarrow \cdots \end{array}$$

This is introduced so I can say the differential is a morphism of degree 1, homotopy is a morphism of degree -1, and makes defining Hom^{\bullet} just slightly easier.

Sometimes we will denote a complex just by A, B, \dots instead of $A^\bullet, B^\bullet, \dots$ to simplify notation.

Next we define the *category of chain complexes* in \mathcal{A} , denoted by $\text{Ch}(\mathcal{A})$, as the following additive category.

Objects: chain complexes in \mathcal{A} .
Morphisms: $\text{Hom}_{\text{Ch}(\mathcal{A})}(A, B)$ is the set of chain maps $A \rightarrow B$, equipped with a group structure inherited from \mathcal{A} by applying operations componentwise.

The composition law is defined componentwise and is clearly associative and bilinear. The identity morphisms id_{A^\bullet} are defined to be $(\text{id}_{A^i})_{i \in \mathbf{Z}}$. The complex $\cdots \rightarrow 0 \rightarrow 0 \rightarrow \cdots$ plays the role of the zero object in $\text{Ch}(\mathcal{A})$ and the biproduct of complexes A and B exists and is witnessed by the chain complex

$$A \oplus B = \left((A^i \oplus B^i)_{i \in \mathbf{Z}}, (d_A^i \oplus d_B^i)_{i \in \mathbf{Z}} \right),$$

together with the canonical projection and injection morphisms arising from biproducts componentwise.

Additionally, we also define the following full additive subcategories of $\text{Ch}(\mathcal{A})$.

$\text{Ch}^+(\mathcal{A})$ *Category of complexes bounded below*, spanned on complexes in \mathcal{A} bounded below.
 $\text{Ch}^-(\mathcal{A})$ *Category of complexes bounded above*, spanned on complexes in \mathcal{A} bounded above.
 $\text{Ch}^b(\mathcal{A})$ *Category of bounded complexes*, spanned on bounded complexes in \mathcal{A} .

Remark 1.28. Whenever \mathcal{A} is k -linear, all the categories of complexes $\text{Ch}^*(\mathcal{A})$ become k -linear as well in the obvious way.

On all the categories of complexes mentioned above, we can now define the translation functor

$$T: \text{Ch}^*(\mathcal{A}) \rightarrow \text{Ch}^*(\mathcal{A})$$

given by its action on objects and morphisms as follows.

Objects: $T(A^\bullet) = A^\bullet[1]$ is the chain complex with $(A^\bullet[1])^i := A^{i+1}$ and differentials $d_{A[1]}^i = -d_A^{i+1}$.
Morphisms: For a chain map $f^\bullet: A^\bullet \rightarrow B^\bullet$ we define $f^\bullet[1]$ to have component maps $(f^\bullet[1])^i = f^{i+1}$.

The translation functor T thus acts on a complex A^\bullet by twisting its differential by a sign and shifting it one step to the *left*, which is pictured below.

$$\begin{array}{ccccccc} & & \dots & & -1 & & 0 & & 1 & & 2 & & \dots \\ A^\bullet & & \dots & \longrightarrow & A^{-1} & \longrightarrow & A^0 & \longrightarrow & A^1 & \longrightarrow & A^2 & \longrightarrow & \dots \\ A^\bullet[1] & & \dots & \longrightarrow & A^0 & \longrightarrow & A^1 & \longrightarrow & A^2 & \longrightarrow & A^3 & \longrightarrow & \dots \end{array}$$

Remark 1.29. We remark that the translation functor T is clearly also additive or k -linear, whenever \mathcal{A} is additive or k -linear.

Since T is an auto-equivalence there exists a quasi-inverse T^{-1} to T , which is defined and unique up to a natural isomorphism. We may then speak of T^k for any $k \in \mathbf{Z}$, whose action on a complex A^\bullet is described by $(A^\bullet[k])^i = A^{i+k}$ with differential $d_{A[k]}^i = (-1)^k d_A^{i+k}$.

Homotopy category of chain complexes

In this subsection we construct the homotopy category of chain complexes associated to a given additive category \mathcal{A} and equip it with a triangulated structure. The main motivation for its introduction in this work is the fact that we will later on use it to construct the derived category of \mathcal{A} . In particular the homotopy category of \mathcal{A} , as opposed to the category of complexes² $\text{Ch}(\mathcal{A})$, can be enhanced with a triangulated structure which will afterwards descend to the level of derived categories.

Definition 1.30. Let f^\bullet and g^\bullet be two chain maps in $\text{Hom}_{\text{Ch}(\mathcal{A})}(A^\bullet, B^\bullet)$. We define f^\bullet and g^\bullet to be *homotopic*, if there exists a collection of morphisms $(h^i: A^i \rightarrow B^{i-1})_{i \in \mathbb{Z}}$, satisfying

$$f^i - g^i = h^{i+1} \circ d_A^i + d_B^{i-1} \circ h^i$$

for all $i \in \mathbb{Z}$. The collection of morphisms $(h^i)_{i \in \mathbb{Z}}$ is called a *homotopy* and we denote f^\bullet and g^\bullet being homotopic by $f^\bullet \simeq g^\bullet$.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & A^{i-1} & \xrightarrow{d_A^{i-1}} & A^i & \xrightarrow{d_A^i} & A^{i+1} \longrightarrow \cdots \\ & & \downarrow f^{i-1} & \nearrow h^i & \downarrow f^i & \nearrow h^{i+1} & \downarrow f^{i+1} \\ \cdots & \longrightarrow & B^{i-1} & \xrightarrow{d_B^{i-1}} & B^i & \xrightarrow{d_B^i} & B^{i+1} \longrightarrow \cdots \end{array}$$

We say f^\bullet is *nullhomotopic*, if $f^\bullet \simeq 0$.

Lemma 1.31. Let A^\bullet, B^\bullet and C^\bullet be complexes in $\text{Ch}(\mathcal{A})$ and let $f, f' \in \text{Hom}_{\text{Ch}(\mathcal{A})}(A^\bullet, B^\bullet)$ and $g, g' \in \text{Hom}_{\text{Ch}(\mathcal{A})}(B^\bullet, C^\bullet)$ be chain maps.

(i) The subset of all nullhomotopic chain maps in $A^\bullet \rightarrow B^\bullet$ forms a submodule of $\text{Hom}_{\text{Ch}(\mathcal{A})}(A^\bullet, B^\bullet)$.

(ii) If $f \simeq f'$ and $g \simeq g'$, then $g \circ f \simeq g' \circ f'$.

Proof. For (i) see [Mil, Ch. 3, 1.3.1]. Claim (ii) is a direct consequence of [Mil, Ch. 3, 1.3.2]. \square

Pick one notation convention, sometimes its f, f' , sometimes its f_0, f_1, \dots

The homotopy category of complexes in \mathcal{A} , denoted by $K(\mathcal{A})$, is defined to be an additive category consisting of

$$\begin{array}{ll} \text{Objects:} & \text{chain complexes in } \mathcal{A}. \\ \text{Morphisms:} & \text{Hom}_{K(\mathcal{A})}(X, Y) := \text{Hom}_{\text{Ch}(\mathcal{A})}(X, Y) / \simeq \end{array}$$

The composition law descends to the quotient by lemma 1.31 (ii), i.e. $[g] \circ [f] := [g \circ f]$, for composable $[f]$ and $[g]$, and for any A^\bullet the identity morphism is defined to be $[\text{id}_{A^\bullet}]$. All the hom-sets $\text{Hom}_{K(\mathcal{A})}(X, Y)$ are k -modules by lemma 1.31 (i) and compositions are k -bilinear maps. The biproduct of two complexes A^\bullet and B^\bullet consists of an object $A^\bullet \oplus B^\bullet$ corresponding to the usual biproduct in $\text{Ch}(\mathcal{A})$ together with the homotopy classes of structure maps of its $\text{Ch}(\mathcal{A})$ -counterpart.

TRIANGULATED STRUCTURE ON $K(\mathcal{A})$. We now shift³ our focus to the construction of a triangulated structure on $K(\mathcal{A})$. The translation functor $T: K(\mathcal{A}) \rightarrow K(\mathcal{A})$ is defined on objects and morphisms in the following way.

²It is still possible to construct the derived category of \mathcal{A} without passing through the homotopy category of complexes, however equipping it with a triangulated structure in that case becomes less elegant.

³Pun intended.

$$\begin{aligned} \text{Objects: } & A^\bullet \mapsto A^\bullet[1]. \\ \text{Morphisms: } & [f^\bullet] \mapsto [f^\bullet[1]]. \end{aligned}$$

This assignment is clearly well defined on morphisms, as $f \simeq f'$ implies $f[1] \simeq f'[1]$.

The other piece of data required to obtain a triangulated category is a collection of *distinguished triangles*. To describe what distinguished triangles are in the case of $\mathbf{K}(\mathcal{A})$, we must first introduce the mapping cone of a morphism of complexes and to this end we will for a moment step outside the scope of the homotopy category of complexes back into the category of chain complexes.

Definition 1.32. Let $f: A^\bullet \rightarrow B^\bullet$ be a morphism of complexes in $\mathbf{Ch}(\mathcal{A})$. The complex $C(f)^\bullet$ is specified by the collection of objects

$$C(f)^i := A^{i+1} \oplus B^i$$

and differentials

$$d_{C(f)}^i := \begin{pmatrix} -d_A^{i+1} & 0 \\ f^{i+1} & d_B^i \end{pmatrix} = \begin{pmatrix} d_{A[1]}^i & 0 \\ f[1]^i & d_B^i \end{pmatrix}, \quad (1.2)$$

for all $i \in \mathbf{Z}$, is called the *cone of f* .

Remark 1.33. Using matrix notation here might be a bit misleading at first. Formally, matrix (1.2) represents the morphism

$$\langle \langle -d_A^{i+1}, 0 \rangle, \langle f^{i+1}, d_B^i \rangle \rangle = \langle \langle -d_A^{i+1}, f^{i+1} \rangle, \langle 0, d_B^i \rangle \rangle$$

according to our convention for defining morphisms from and into biproducts. A simple matrix calculation, using the fact that f is a chain map and d_A, d_B differentials, shows that $C(f)^\bullet$ is indeed a chain complex.

Remark 1.34. The naming convention of course comes from topology, where one can show that the singular chain complex associated to the topological mapping cone $M(f)$ of a continuous map $f: X \rightarrow Y$ is chain homotopically equivalent to the cone of the chain map induced by f between singular chain complexes of X and Y .

this remark can be skipped

Along with the cone of a chain map f we also introduce two chain maps

$$\tau_f: B^\bullet \rightarrow C(f)^\bullet,$$

given by the collection $(\tau_f^i: B^i \rightarrow A^{i+1} \oplus B^i)_{i \in \mathbf{Z}}$, where τ_f^i is the canonical injection into the biproduct for all $i \in \mathbf{Z}$, and

$$\pi_f: C(f)^\bullet \rightarrow A^\bullet[1],$$

given by the collection $(\pi_f^i: A^{i+1} \oplus B^i \rightarrow A^{i+1})_{i \in \mathbf{Z}}$, where π_f^i is the canonical projection from the biproduct for all $i \in \mathbf{Z}$.

Definition 1.35. We define any triangle in $\mathbf{K}(\mathcal{A})$ isomorphic to a triangle of the form

$$A^\bullet \xrightarrow{f} B^\bullet \xrightarrow{\tau_f} C(f)^\bullet \xrightarrow{\pi_f} A[1]^\bullet \quad (1.3)$$

to be distinguished.

Proposition 1.36. *The homotopy category $\mathbf{K}(\mathcal{A})$ together with the translation functor $T: \mathbf{K}(\mathcal{A}) \rightarrow \mathbf{K}(\mathcal{A})$ and distinguished triangles defined above is a triangulated category.*

Proof.

□

Very detailed proof is given in [Mil, Ch. 3, 2.1.]

As in the case of categories of complexes in \mathcal{A} , we can also define the following full additive subcategories of $K(\mathcal{A})$.

- $K^+(\mathcal{A})$ Homotopy category of complexes bounded below, spanned on complexes in \mathcal{A} bounded below.
- $K^-(\mathcal{A})$ Homotopy category of complexes bounded above, spanned on complexes in \mathcal{A} bounded above.
- $K^b(\mathcal{A})$ Homotopy category of bounded complexes, spanned on bounded complexes in \mathcal{A} .

For convenience we will in practice assume that unless otherwise stated our complexes A^\bullet in $K^+(\mathcal{A})$ will be supported in $\mathbf{Z}_{\geq 0}$ i.e. we will assume $A^i \simeq 0$ for $i < 0$.

Remark 1.37. By proposition 1.16 all the subcategories $K^+(\mathcal{A})$, $K^-(\mathcal{A})$, $K^b(\mathcal{A})$ of $K(\mathcal{A})$ are triangulated.

Cohomology

A very important invariant of a chain complex in the homotopy category, which measures the extent to which it fails to be exact, is its cohomology. Here we are no longer assuming \mathcal{A} is just k -linear, but abelian, since we will need kernels and cokernels to exist. For a chain complex A^\bullet in $\text{Ch}(\mathcal{A})$ and $i \in \mathbf{Z}$ we define its i -th cohomology to be

$$H^i(A^\bullet) := \text{coker}(\text{im } d^{i-1} \rightarrow \ker d^i).$$

Remark 1.38. A computation with universal properties inside an abelian category shows, that the following are all equivalent ways of defining the cohomology of a complex as well

$$\begin{aligned} H^i(A^\bullet) &:= \text{coker}(\text{im } d^{i-1} \rightarrow \ker d^i) \simeq \ker(\text{coker } d^{i-1} \rightarrow \text{im } d^i) \\ &\simeq \text{coker}(A^{i-1} \rightarrow \ker d^i) \simeq \ker(\text{coker } d^{i-1} \rightarrow A^i). \end{aligned}$$

See [KS06, Def. 8.3.8. (i)].

For a morphism of complexes $f^\bullet: A^\bullet \rightarrow B^\bullet$ one can also define a morphism

$$H^i(f^\bullet): H^i(A^\bullet) \rightarrow H^i(B^\bullet)$$

in \mathcal{A} , because f^\bullet induces maps $\text{im } d_A^{i-1} \rightarrow \text{im } d_B^{i-1}$ and $\ker d_A^i \rightarrow \ker d_B^i$, which fit into the commutative diagram below.

$$\begin{array}{ccccc} B^{i-1} & \xrightarrow{d_B^{i-1}} & B^i & \xrightarrow{d_B^i} & B^{i+1} \\ \uparrow & & \uparrow & & \uparrow \\ A^{i-1} & \xrightarrow{d_A^{i-1}} & A^i & \xrightarrow{d_A^i} & A^{i+1} \\ & \searrow & \nearrow & \searrow & \nearrow \\ & \text{im } d_B^{i-1} & & \ker d_B^i & \\ & \uparrow & & \uparrow & \\ & \text{im } d_A^{i-1} & & \ker d_A^i & \\ & \searrow & & \searrow & \\ & & H^i(B^\bullet) & & \\ & \uparrow & \uparrow & & \\ & & H^i(A^\bullet) & & \end{array} \quad (1.4)$$

All the induced morphisms come from universal properties and are as such unique for which the diagram commutes. Thus the assignment

$$f^\bullet \mapsto H^i(f^\bullet): \operatorname{Hom}_{\operatorname{Ch}(\mathcal{A})}(A, B) \rightarrow \operatorname{Hom}_{\mathcal{A}}(H^i(A), H^i(B))$$

is functorial i.e. respects composition and maps identity morphisms to identity morphisms. For the same reasons it is also a k -linear homomorphism, showing that

$$H^i: \operatorname{Ch}(\mathcal{A}) \rightarrow \mathcal{A}$$

a k -linear functor. Due to the following proposition 1.39, the i -th cohomology functor H^i descends to a well defined additive functor

$$H^i: \operatorname{K}(\mathcal{A}) \rightarrow \mathcal{A}$$

on the homotopy category $\operatorname{K}(\mathcal{A})$.

Proposition 1.39. *Let $f: A^\bullet \rightarrow B^\bullet$ be a nullhomotopic chain map in $\operatorname{Ch}(\mathcal{A})$. Then f induces the zero map on cohomology, that is $H^i(f) = 0$ for all $i \in \mathbf{Z}$.*

Proof. As f is nullhomotopic, there exists a homotopy $(h^i: A^i \rightarrow B^{i-1})_{i \in \mathbf{Z}}$ such that

$$f^i = h^{i+1}d_A^i + d_B^{i-1}h^i \quad \text{for all } i \in \mathbf{Z}.$$

Let us name the following morphisms from diagram (1.4).

$$\begin{array}{ll} i_A: \ker d_A^i \hookrightarrow A^i & i_B: \ker d_B^i \hookrightarrow B^i \\ \psi_B: B^{i-1} \twoheadrightarrow \operatorname{im} d_B^{i-1} & \xi_B: \operatorname{im} d_B^{i-1} \rightarrow \ker d_B^i \\ \pi_B: \ker d_B^i \twoheadrightarrow H^i(B^\bullet) & \phi: \ker d_A^i \rightarrow \ker d_B^i \end{array}$$

We compute $i_B \phi = f^i i_A = (h^{i+1}d_A^i + d_B^{i-1}h^i)i_A = d_B^{i-1}h^i i_A = i_B \xi_B \psi_B h^i i_A$. Since i_B is a monomorphism, we may cancel it on the left, to express ϕ as $\xi_B \psi_B h^i i_A$. Then it is clear, that $\pi_B \phi = 0$ (as $\pi_B \xi_B = 0$), which means that 0 is the unique map $H^i(A^\bullet) \rightarrow H^i(B^\bullet)$ fitting into the commutative diagram (1.4). □

It is very fruitful to consider all the cohomology functors $(H^i)_{i \in \mathbf{Z}}$ at once, as is witnessed by the next proposition.

ugly but uses only universal properties, no elements

Proposition 1.40. *[KS06, Theorem 12.3.3.] Let $0 \rightarrow A^\bullet \rightarrow B^\bullet \rightarrow C^\bullet \rightarrow 0$ be a short exact sequence in $\operatorname{Ch}(\mathcal{A})$. Then there exists a long exact sequence in \mathcal{A}*

$$\cdots \rightarrow H^i(A^\bullet) \rightarrow H^i(B^\bullet) \rightarrow H^i(C^\bullet) \rightarrow H^{i+1}(A^\bullet) \rightarrow \cdots,$$

which is functorial in the short exact sequence.

Remark 1.41. Morphisms $H^i(A^\bullet) \rightarrow H^i(B^\bullet)$ and $H^i(B^\bullet) \rightarrow H^i(C^\bullet)$ are induced by the corresponding morphisms between complexes. But the existence of a *connecting* morphism $H^i(C^\bullet) \rightarrow H^{i+1}(A^\bullet)$ is part of the assertion of the proposition.

An elementary observation shows that for all $i \in \mathbf{Z}$ the following natural equivalence exists

$$H^0 \circ T^i \simeq H^i, \tag{1.5}$$

so the long exact sequence of proposition 1.40 can be rephrased as

$$\cdots \rightarrow H^0(A^\bullet[i]) \rightarrow H^0(B^\bullet[i]) \rightarrow H^0(C^\bullet[i]) \rightarrow H^0(A^\bullet[i+1]) \rightarrow \cdots.$$

Proposition 1.42. *With respect to the triangulated structure on $\mathbf{K}(\mathcal{A})$ the cohomology functors H^i are cohomological.*

Proof. First, it is enough to show only that

$$H^0(B^\bullet) \rightarrow H^0(C(f)^\bullet) \rightarrow H^0(A[1]^\bullet)$$

is exact for any distinguished triangle of the form (1.3). This statement becomes apparent, once we realize that the distinguished triangle yields a short exact sequence

$$0 \longrightarrow B^\bullet \xrightarrow{\tau_f} C(f)^\bullet \xrightarrow{\pi_f} A[1]^\bullet \longrightarrow 0$$

in $\mathbf{Ch}(\mathcal{A})$ to which one then applies proposition 1.40⁴.

Now we argue why this is enough to show that all H^i are cohomological. Since every distinguished triangle in $\mathbf{K}(\mathcal{A})$ is isomorphic to a triangle of the form (1.3) we see that the sequence $H^0(B^\bullet) \rightarrow H^0(C^\bullet) \rightarrow H^0(A[1]^\bullet)$ is exact for any distinguished triangle $A^\bullet \rightarrow B^\bullet \rightarrow C^\bullet \rightarrow A[1]^\bullet$ by functoriality of H^i . Rotating the preceding triangle i.e. periodically applying the translation functor or its quasi-inverse (both preserving distinguishness of triangles by axiom **TR2**) shows that H^0 is cohomological. Finally, by (1.5) clearly all H^i are cohomological. \square

To end this section, we introduce a class of morphisms and a class of objects in $\mathbf{K}(\mathcal{A})$, playing a principal role in the sequel.

Definition 1.43. Let A^\bullet and B^\bullet be objects and $f: A^\bullet \rightarrow B^\bullet$ a morphism of $\mathbf{K}(\mathcal{A})$.

- (i) Chain complex A^\bullet is said to be *acyclic*, if $H^i(A^\bullet) \simeq 0$ for all $i \in \mathbf{Z}$.
- (ii) Morphism f is a *quasi-isomorphism*, if $H^i(f): H^i(A^\bullet) \rightarrow H^i(B^\bullet)$ is an isomorphism for all $i \in \mathbf{Z}$.

⁴Note that we have actually used much less than what the proposition has to offer.

2 Derived categories

The first goal of this section is to construct the derived category of an abelian category \mathcal{A} and equip it with a triangulated structure. Our arguments, although specialized to the homotopy category $K(\mathcal{A})$ and the class of quasi-isomorphisms, do not differ tremendously from the general theory of localization of categories. A more comprehensive and formal treatment of this topic is laid out in [KS06, Ch. 7] or [Mil]. The second part covers the construction of derived functors. We see how the established framework of derived categories nicely lends itself for the definition of derived functors and we also relate them back to the classical higher derived functors. We close the section by establishing a correspondence between the hom-sets of $D^+(\mathcal{A})$ and certain Ext-modules.

2.1 Derived category of an abelian category

In algebraic geometry cohomology of a geometric object, like a scheme or a variety, X with respect to some coherent sheaf \mathcal{F} plays a very important role. One way of computing $H^i(X, \mathcal{F})$, which we shall also feature in section 3, involves the following. Instead of intrinsically studying the sheaf \mathcal{F} , we represent it with a so called *resolution*, which consists of a complex of sheaves F^\bullet , built up from sheaves F^i , for $i \in \mathbb{Z}$, belonging to some class of sheaves, which is well behaved under cohomology, and a quasi-isomorphism of the form $F^\bullet \rightarrow \mathcal{F}$ or $\mathcal{F} \rightarrow F^\bullet$. After noting that the sheaf \mathcal{F} can be seen as a complex concentrated in degree 0 and observing that replacing a resolution of \mathcal{F} with another one results in computing isomorphic cohomology groups, we are motivated not to distinguish the sheaf \mathcal{F} from its resolutions in the ambient (homotopy) category of complexes any longer. Taking a step back, we would like to modify the homotopy category $K(\text{coh}(X))$ in such a way that \mathcal{F} is identified with all its resolutions, or in other words, we want all the quasi-isomorphisms of $K(\text{coh}(X))$ to turn into isomorphisms in a “universal way”. We will take the latter to be our inspiration for the definition of a derived category $D(\mathcal{A})$ of a general abelian category \mathcal{A} . This is stated more formally in the form of the ensuing universal property.

intrinsically might not be the best word as resolutions in certain cases do represent a sheaf intrinsically in the sense of generators and relations... (Hilbert syzygy thm)

Definition 2.1. Let \mathcal{A} be an abelian category and $K(\mathcal{A})$ its homotopy category. A triangulated category $D(\mathcal{A})$ together with a triangulated functor $Q: K(\mathcal{A}) \rightarrow D(\mathcal{A})$ is the *derived category of \mathcal{A}* , if it satisfies:

1. For every quasi-isomorphism s in $K(\mathcal{A})$, $Q(s)$ is an isomorphism in $D(\mathcal{A})$.
2. For any triangulated category \mathcal{D} and any functor $F: K(\mathcal{A}) \rightarrow \mathcal{D}$, sending quasi-isomorphisms s in $K(\mathcal{A})$ to isomorphisms $F(s)$ in \mathcal{D} , there exists a triangulated functor $F_0: D(\mathcal{A}) \rightarrow \mathcal{D}$, which is unique up to a unique natural isomorphism, such that $F \simeq F_0 \circ Q$. In other words, the diagram below commutes up to natural isomorphism.

$$\begin{array}{ccc} K(\mathcal{A}) & \xrightarrow{F} & \mathcal{D} \\ Q \downarrow & \nearrow F_0 & \\ D(\mathcal{A}) & & \end{array}$$

Remark 2.2. We recognize this definition as a special case of localization of categories [KS06, Definition 7.1.1.]. In particular it defines $D(\mathcal{A})$ to be the *localization of a triangulated category $K(\mathcal{A})$* by the family of all quasi-isomorphisms in $K(\mathcal{A})$.

A naive way of constructing $D(\mathcal{A})$ out of $K(\mathcal{A})$ would be to artificially add the inverses to all the quasi-isomorphisms in $K(\mathcal{A})$ and then impose the correct collection of relations

on the newly constructed class of morphisms. As this can quickly lead us to some set theoretic problems, we will construct a specific model, which achieves this, instead. Our construction is a priori not going to result in a locally small⁵ category, but as we shall soon see in practice all the categories we will be concerned with will be locally small.

To start, we first need a technical lemma resembling the Ore condition from non-commutative algebra.

Lemma 2.3. *Let $f: A^\bullet \rightarrow B^\bullet$ and $s: C^\bullet \rightarrow B^\bullet$ belong to the homotopy category $K(\mathcal{A})$, with s being a quasi-isomorphism. Then there exists a quasi-isomorphism $u: C_0^\bullet \rightarrow A^\bullet$ and a morphism $g: C_0^\bullet \rightarrow C^\bullet$, such that the diagram below commutes in $K(\mathcal{A})$.*

$$\begin{array}{ccc} C_0^\bullet & \xrightarrow{\quad g \quad} & C^\bullet \\ \downarrow \sim u & & \downarrow \sim s \\ A^\bullet & \xrightarrow{\quad f \quad} & B^\bullet \end{array}$$

Proof.

□

add proof

Equipped with the preceding lemma, we are now in a position to construct the derived category $D(\mathcal{A})$ of an abelian category \mathcal{A} . The derived category $D(\mathcal{A})$ will consist of

Objects of $D(\mathcal{A})$: chain complexes in \mathcal{A} ,

i.e. the class of objects of $K(\mathcal{A})$ or $\text{Ch}(\mathcal{A})$, and a class of morphisms, which is a bit more intricate to define. For fixed complexes A^\bullet and B^\bullet we define the hom-set⁶ $\text{Hom}_{D(\mathcal{A})}(A^\bullet, B^\bullet)$ in the following way.

HOM-SETS. A *left roof spanned on A^\bullet and B^\bullet* is a pair of morphisms $s: A^\bullet \rightarrow C^\bullet$ and $f: C^\bullet \rightarrow B^\bullet$ in the homotopy category $K(\mathcal{A})$, where s is a quasi-isomorphism. This roof is depicted in the following diagram

$$\begin{array}{ccc} & C^\bullet & \\ \swarrow \sim s & & \searrow f \\ A^\bullet & & B^\bullet \end{array} \tag{2.1}$$

or denoted by (s, f) . Dually, one also obtains the notion of a *right roof spanned on A^\bullet and B^\bullet* , which is a pair of morphisms $g: A^\bullet \rightarrow C^\bullet$ and $u: B^\bullet \rightarrow C^\bullet$, where u is a quasi-isomorphism, and is depicted below.

$$\begin{array}{ccc} & C^\bullet & \\ \nearrow g & & \nwarrow \sim u \\ A^\bullet & & B^\bullet \end{array}$$

Our construction of $\text{Hom}_{D(\mathcal{A})}(A^\bullet, B^\bullet)$ will be based on left roofs, for nothing is gained or lost by picking either one of the two. Both work just as well and are in fact equivalent. Despite our arbitrary choice, it is still beneficial to consider both, as we will sometimes switch between the two whenever convenient.

⁵A category \mathcal{C} is called *locally small* if for all objects X and Y of \mathcal{C} the hom-sets $\text{Hom}_{\mathcal{C}}(X, Y)$ are actual sets.

⁶What will be defined here is a priori not necessarily a set, but a class, so $D(\mathcal{A})$, defined in this section, is not a category in the usual sense. We will however prove that in specific cases some variants of the derived category, especially concrete ones used later on, will from categories in the usual sense.

Definition 2.4. Two left roofs $A^\bullet \xleftarrow{s_0} C_0^\bullet \xrightarrow{f_0} B^\bullet$ and $A^\bullet \xleftarrow{s_1} C_1^\bullet \xrightarrow{f_1} B^\bullet$ are defined to be *equivalent*, if there exists a quasi-isomorphism $u: C^\bullet \rightarrow C_0^\bullet$ and a morphism $g: C^\bullet \rightarrow C_1^\bullet$ in $K(\mathcal{A})$, for which the diagram below commutes (in $K(\mathcal{A})$).

$$\begin{array}{ccccc}
 & & C^\bullet & & \\
 & \swarrow \sim & & \searrow & \\
 & C_0^\bullet & & C_1^\bullet & \\
 & \swarrow \sim & & \searrow & \\
 A^\bullet & & & & B^\bullet
 \end{array}
 \quad (2.2)$$

We denote this relation by \equiv .

Note that since $C^\bullet \rightarrow C_0^\bullet \rightarrow A^\bullet$ is a quasi-isomorphism, the same is true for the composition $C^\bullet \rightarrow C_1^\bullet \rightarrow A^\bullet$, concluding that $g: C^\bullet \rightarrow C_1^\bullet$ is a quasi-isomorphism. Also observe that in the diagram (2.2) we may find a new left roof, namely

$$\begin{array}{ccc}
 & C^\bullet & \\
 s_0 \circ u \swarrow \sim & & \searrow f_1 \circ g \\
 A^\bullet & & B^\bullet,
 \end{array}$$

which is also equivalent to the two roofs we started with (s_0, f_0) and (s_1, f_1) .

Lemma 2.5. *The equivalence of left roofs on A^\bullet and B^\bullet is an equivalence relation.*

Proof. The relation is clearly reflexive. We take both u and g to be id_{C^\bullet} . By the note above it is also symmetric, for g is a quasi-isomorphism. It remains to show transitivity. Suppose left roofs $A^\bullet \leftarrow C_0^\bullet \rightarrow B^\bullet$ and $A^\bullet \leftarrow C_1^\bullet \rightarrow B^\bullet$ are equivalent and left roofs $A^\bullet \leftarrow C_1^\bullet \rightarrow B^\bullet$ and $A^\bullet \leftarrow C_2^\bullet \rightarrow B^\bullet$ are equivalent. This is witnessed by the diagrams

$$\begin{array}{ccc}
 \begin{array}{ccccc}
 & & D_0^\bullet & & \\
 & \swarrow \sim & & \searrow & \\
 & C_0^\bullet & & C_1^\bullet & \\
 & \swarrow \sim & & \searrow & \\
 A^\bullet & & & & B^\bullet
 \end{array}
 & \text{and} &
 \begin{array}{ccccc}
 & & D_1^\bullet & & \\
 & \swarrow \sim & & \searrow & \\
 & C_1^\bullet & & C_2^\bullet & \\
 & \swarrow \sim & & \searrow & \\
 A^\bullet & & & & B^\bullet
 \end{array}
 \end{array}$$

By lemma 2.3 the right roof $D_0^\bullet \rightarrow C_1^\bullet \leftarrow D_1^\bullet$ may be completed to form a commutative square

$$\begin{array}{ccc}
 C^\bullet & \xrightarrow{\quad} & D_1^\bullet \\
 \downarrow \sim & & \downarrow \sim \\
 D_0^\bullet & \xrightarrow{\quad} & C_1^\bullet
 \end{array}$$

proving that $A^\bullet \leftarrow C_0^\bullet \rightarrow B^\bullet$ and $A^\bullet \leftarrow C_2^\bullet \rightarrow B^\bullet$ are equivalent. \square

For a left roof (2.1) we let $[s \setminus f]$ or $\left[A^\bullet \xleftarrow{s} C^\bullet \xrightarrow{f} B^\bullet \right]$ denote its equivalence class under \equiv .

We then define $\text{Hom}_{D(\mathcal{A})}(A^\bullet, B^\bullet)$ to be the class of left roofs spanned by A^\bullet and B^\bullet , quotiented by the relation \equiv . That is

$$\text{Hom}_{D(\mathcal{A})}(A^\bullet, B^\bullet) := \left\{ \left[\begin{array}{ccc} & C^\bullet & \\ \swarrow & & \searrow \\ A^\bullet & & B^\bullet \end{array} \right]_{\equiv} \mid \begin{array}{l} C^\bullet \in \text{Ob } K(\mathcal{A}), \\ f \in \text{Hom}_{K(\mathcal{A})}(C^\bullet, B^\bullet), \\ s \in \text{Hom}_{K(\mathcal{A})}(C^\bullet, A^\bullet) \text{ quasi-iso.} \end{array} \right\}.$$

COMPOSITION. Next we define the composition operations

$$\circ: \text{Hom}_{\mathcal{D}(\mathcal{A})}(A_0^\bullet, A_1^\bullet) \times \text{Hom}_{\mathcal{D}(\mathcal{A})}(A_1^\bullet, A_2^\bullet) \rightarrow \text{Hom}_{\mathcal{D}(\mathcal{A})}(A_0^\bullet, A_2^\bullet),$$

for all objects A_0^\bullet , A_1^\bullet and A_2^\bullet of $\mathcal{D}(\mathcal{A})$. Let $\phi_0: A_0^\bullet \rightarrow A_1^\bullet$ and $\phi_1: A_1^\bullet \rightarrow A_2^\bullet$ be a pair of composable morphisms in $\mathcal{D}(\mathcal{A})$. Next, pick their respective left roof representatives, $A_0^\bullet \xleftarrow{s_0} C_0^\bullet \xrightarrow{f_0} A_1^\bullet$ and $A_1^\bullet \xleftarrow{s_1} C_1^\bullet \xrightarrow{f_1} A_2^\bullet$, and concatenate them according to the solid zig-zag diagram below.

$$\begin{array}{ccccc} & & C^\bullet & & \\ & \swarrow \tilde{\sim} & \swarrow u & \searrow g & \swarrow \tilde{\sim} \\ & C_0^\bullet & & C_1^\bullet & \\ \swarrow \tilde{\sim} & & \searrow f_0 & \swarrow \tilde{\sim} & \searrow f_1 \\ A_0^\bullet & & A_1^\bullet & & A_2^\bullet \end{array}$$

By lemma 2.3 there are morphisms $u: C^\bullet \rightarrow C_0^\bullet$ and $g: C^\bullet \rightarrow C_1^\bullet$, depicted with dashed arrows, completing the diagram in $\mathcal{K}(\mathcal{A})$. In this way we obtain a left roof, formed by a quasi-isomorphism $s_0 \circ u$ and a morphism $f_1 \circ g$, the equivalence class of which we define to be the composition

$$\phi_1 \circ \phi_0 := \left[A_0^\bullet \xleftarrow{s_0 \circ u} C^\bullet \xrightarrow{f_1 \circ g} A_2^\bullet \right].$$

It can be shown that this is a well defined composition that is also associative. We leave out the proof, because it is routine, but refer the reader to a very detailed account by Milićić [Mil, Ch. 1.3].

IDENTITIES. The identity morphism on an object A^\bullet of $\mathcal{D}(\mathcal{A})$ is defined to be the equivalence class of $A^\bullet \xleftarrow{\text{id}_{A^\bullet}} A^\bullet \xrightarrow{\text{id}_{A^\bullet}} A^\bullet$. It is not difficult to check that these classes play the role of identity morphisms in $\mathcal{D}(\mathcal{A})$.

FUNCTOR $Q: \mathcal{K}(\mathcal{A}) \rightarrow \mathcal{D}(\mathcal{A})$. The *localization* functor $Q: \mathcal{K}(\mathcal{A}) \rightarrow \mathcal{D}(\mathcal{A})$ is an identity on objects functor with the action on morphisms defined by the assignment

$$\begin{aligned} \text{Hom}_{\mathcal{K}(\mathcal{A})}(A^\bullet, B^\bullet) &\xrightarrow{Q} \text{Hom}_{\mathcal{D}(\mathcal{A})}(A^\bullet, B^\bullet) \\ (f: A^\bullet \rightarrow B^\bullet) &\mapsto \left[A^\bullet \xleftarrow{\text{id}_{A^\bullet}} A^\bullet \xrightarrow{f} B^\bullet \right]. \end{aligned}$$

k -LINEAR STRUCTURE. To equip the hom-sets of $\mathcal{D}(\mathcal{A})$ with a k -module structure, we consult the following lemma resembling finding a common denominator in the context of left roofs.

Lemma 2.6. *Let $\phi_0: A^\bullet \rightarrow B^\bullet$ and $\phi_1: A^\bullet \rightarrow B^\bullet$ be two morphisms in $\mathcal{D}(\mathcal{A})$ represented by left roofs*

$$\begin{array}{ccc} & C_0^\bullet & \\ \swarrow s_0 & & \searrow f_0 \\ A^\bullet & & B^\bullet \end{array} \quad \text{and} \quad \begin{array}{ccc} & C_1^\bullet & \\ \swarrow s_1 & & \searrow f_1 \\ A^\bullet & & B^\bullet \end{array}$$

Then there is a quasi-isomorphism $s: C^\bullet \rightarrow A^\bullet$ and morphisms $g_0, g_1: C^\bullet \rightarrow B^\bullet$, such that

$$\begin{array}{ccc} & C^\bullet & \\ \swarrow s & & \searrow g_0 \\ A^\bullet & & B^\bullet \end{array} \quad \text{and} \quad \begin{array}{ccc} & C^\bullet & \\ \swarrow s & & \searrow g_1 \\ A^\bullet & & B^\bullet \end{array}$$

represent ϕ_0 and ϕ_1 respectively.

Proof. □

Using notation from lemma 2.6, we define the addition operation on $\text{Hom}_{D(\mathcal{A})}(A^\bullet, B^\bullet)$ by the rule

$$\phi_0 + \phi_1 := \left[A^\bullet \xleftarrow{s} C^\bullet \xrightarrow{g_0+g_1} B^\bullet \right].$$

It is well defined, associative, commutative and has a neutral element $0 = Q(0)$. The action of scalars of the ring k is defined as

$$\lambda\phi_0 := \left[A^\bullet \xleftarrow{s} C^\bullet \xrightarrow{\lambda f_0} B^\bullet \right].$$

Moreover, the composition law \circ is k -bilinear and the localization functor $Q: K(\mathcal{A}) \rightarrow D(\mathcal{A})$ is an additive functor.

TRIANGULATED STRUCTURE. The shift functor $T: D(\mathcal{A}) \rightarrow D(\mathcal{A})$ is defined

Remark 2.7. All that has been defined and established in this section with left roofs can analogously also be done with right roofs.

As with the homotopy category of complexes $K(\mathcal{A})$, we also have the following bounded versions of the derived category $D(\mathcal{A})$, appearing as full triangulated subcategories of the unbounded variant $D(\mathcal{A})$ by proposition 1.16.

$$\begin{aligned} D^+(\mathcal{A}) & \text{ spanned on objects of } K^+(\mathcal{A}). \\ D^-(\mathcal{A}) & \text{ spanned on objects of } K^-(\mathcal{A}). \\ D^b(\mathcal{A}) & \text{ spanned on objects of } K^b(\mathcal{A}). \end{aligned}$$

maybe add that the constructed $D(\mathcal{A})$ satisfies the universal property form the beginning. Later it can be referenced when considering functors going out of $D(\mathcal{A})$.

2.1.1 Derived category of an abelian category with enough injectives

After possibly working with proper classes when constructing the derived category, this section will once again place us back on familiar grounds of set theory. Aside from these concerns the establishing result of this section will have a very important practical application – construction of derived functors. Under an assumption on the abelian category \mathcal{A} , we will establish an equivalence of $D^+(\mathcal{A})$ with the homotopy category of a full additive subcategory of \mathcal{A} , spanned on *injective objects*, which we define presently.

Definition 2.8. An object I of an abelian category \mathcal{A} is *injective*⁷, if the functor

$$\text{Hom}_{\mathcal{A}}(-, I): \mathcal{A}^{\text{op}} \rightarrow \text{Mod}_k$$

is exact. Equivalently whenever for any monomorphism $A \hookrightarrow B$ and morphism $A \rightarrow I$ there is a morphism $B \rightarrow I$, for which the following diagram commutes.

$$\begin{array}{ccc} & I & \\ & \uparrow & \nwarrow \\ 0 & \longrightarrow A & \hookrightarrow B \end{array}$$

A category \mathcal{A} is said to *have enough injectives*, if every object A of \mathcal{A} embeds into an injective object i.e. there is a monomorphism $A \hookrightarrow I$ for some injective object I .

⁷Dually, an object P of \mathcal{A} is *projective*, if P is injective in \mathcal{A}^{op} , or more explicitly, the functor $\text{Hom}_{\mathcal{A}}(P, -): \mathcal{A} \rightarrow \text{Mod}_k$ is exact. Category \mathcal{A} is said to *have enough projectives*, if every object A of \mathcal{A} is a quotient of some projective object i.e. there is an epimorphism $P \twoheadrightarrow A$ for some projective object P .

Remark 2.9. A simple verification shows, that the full subcategory of an abelian or k -linear category \mathcal{A} , spanned on all injective objects of \mathcal{A} is a k -linear category, as the zero object 0 is injective and the biproduct of two injective objects is again injective. We denote this category by \mathcal{J} .

We will use injectives to

We call a quasi-isomorphism $f: A^\bullet \rightarrow I^\bullet$ an *injective resolution* of the complex A^\bullet . Later we will also see that this injective resolution is unique up to homotopy i.e. any two injective resolutions of A^\bullet are homotopically equivalent. Throughout this section differentials of I^\bullet will be denoted with $\delta^i: I^i \rightarrow I^{i+1}$.

Proposition 2.10. *Suppose \mathcal{A} contains enough injectives. Then for every A^\bullet in $K^+(\mathcal{A})$ there is a quasi-isomorphism $f^\bullet: A^\bullet \rightarrow I^\bullet$, where $I^\bullet \in \text{Ob } K^+(\mathcal{A})$ is a complex of injectives.*

Proof. We will inductively construct a complex I^\bullet in $K^+(\mathcal{A})$, built up from injectives, and a quasi-isomorphism $f^\bullet: A^\bullet \rightarrow I^\bullet$. For simplicity assume $A^i = 0$ for $i < 0$.

The base case is trivial. Define $I^i = 0$ and $f^i = 0$ for $i < 0$ and take $f^0: A^0 \rightarrow I^0$ to be the morphism obtained from the assumption about \mathcal{A} having enough injectives.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & 0 & \longrightarrow & A^0 & \longrightarrow & A^1 \longrightarrow \cdots \\ & & & & \downarrow & & \\ \cdots & \longrightarrow & 0 & \longrightarrow & I^0 & & \end{array}$$

For the induction step suppose we have constructed the complex I^\bullet and the morphism f^\bullet up to index n .

$$\begin{array}{ccccccc} \cdots & \longrightarrow & A^{n-1} & \xrightarrow{d^{n-1}} & A^n & \xrightarrow{d^n} & A^{n+1} \longrightarrow \cdots \\ & & \downarrow f^{n-1} & & \downarrow f^n & & \\ \cdots & \longrightarrow & I^{n-1} & \xrightarrow{\delta^{n-1}} & I^n & & \end{array}$$

Consider the cokernel of $d_{C(f)}^{n-1}$

$$A^n \oplus I^{n-1} \xrightarrow{d_{C(f)}^{n-1}} A^{n+1} \oplus I^n \xrightarrow{e} \text{coker } d_{C(f)}^{n-1}$$

and denote with $j: \text{coker } d_{C(f)}^{n-1} \hookrightarrow I^{n+1}$ an embedding to an injective object I^{n+1} . After precomposing the morphism

$$A^{n+1} \oplus I^n \xrightarrow{e} \text{coker } d_{C(f)}^{n-1} \xrightarrow{j} I^{n+1}$$

with canonical embeddings of A^{n+1} and I^n into their biproduct $A^{n+1} \oplus I^n$, we obtain morphisms $\delta^n: I^n \rightarrow I^{n+1}$ and $f^{n+1}: A^{n+1} \rightarrow I^{n+1}$. As $j \circ e$ is a morphism fitting into the following coproduct diagram,

$$\begin{array}{ccc} A^{n+1} & & I^n \\ & \searrow & \swarrow \\ & A^{n+1} \oplus I^n & \\ & \downarrow j \circ e & \\ & I^{n+1} & \end{array} \quad \begin{array}{c} f^{n+1} \nearrow \\ \delta^n \searrow \end{array}$$

we see that $j \circ e = \langle f^{n+1}, \delta^n \rangle$. Next, we see that $\delta^n \delta^{n-1} = 0$ and $\delta^n f^n = f^{n+1} d^n$ from the computation

$$0 = j \circ e \circ d_{C(f)}^{n-1} = \langle f^{n+1}, \delta^n \rangle \begin{pmatrix} -d^n & 0 \\ f^n & \delta^{n-1} \end{pmatrix} = \langle \delta^n f^n - f^{n+1} d^n, \delta^n \delta^{n-1} \rangle$$

Thus far we have constructed a chain complex I^\bullet of injective objects and a chain map $f: A^\bullet \rightarrow I^\bullet$. It remains to be shown that f is a quasi-isomorphism. Recall, that f is a quasi-isomorphism if and only if its cone $C(f)^\bullet$ is acyclic. By remark 1.38, we know

$$H^n(C(f)^\bullet) = \ker(\text{coker } d_{C(f)}^{n-1} \xrightarrow{d} A^{n+2} \oplus I^{n+1}),$$

where d is obtained from the universal property of $\text{coker } d_{C(f)}^{n-1}$, induced by $d_{C(f)}^n$. Thus it suffices to show, that d is a monomorphism. Consider the following diagram, which we will show to commute.

$$\begin{array}{ccccc} A^n \oplus I^{n-1} & \xrightarrow{d_{C(f)}^{n-1}} & A^{n+1} \oplus I^n & \xrightarrow{d_{C(f)}^n} & A^{n+2} \oplus I^{n+1} \\ & & \searrow e & \nearrow d & \searrow p \\ & & \text{coker } d_{C(f)}^{n-1} & \xrightarrow{j} & I^{n+1} \end{array}$$

Once we show, that its right most triangle is commutative, we see that d is monomorphic, because j is monomorphic. To see that the triangle in question commutes, we compute

$$p \circ d \circ e = p \circ d_{C(f)}^n = \langle f^{n+1}, \delta^n \rangle = j \circ e.$$

As e is epic, we may cancel it on the right, to arrive at $p \circ d = j$, which ends the proof. \square

Remark 2.11. As is evident from the proof by close inspection we have only used two facts about the class of all injective objects of \mathcal{A} – that every object of \mathcal{A} embeds into some injective object and that the class of injectives is closed under finite direct sums. This will later on be used in subsection ?? when constructing a right derived functor of a given functor F in the presence of an F -adapted class.

Theorem 2.12. Assume \mathcal{A} contains enough injectives and let $\mathcal{J} \subseteq \mathcal{A}$ denote the full subcategory on injective objects of \mathcal{A} . Then the inclusion $K^+(\mathcal{J}) \hookrightarrow K^+(\mathcal{A})$ induces an equivalence of triangulated categories

$$K^+(\mathcal{J}) \simeq D^+(\mathcal{A}).$$

Remark 2.13. Theorem 2.12 in particular shows that $D^+(\mathcal{A})$ is a category in the usual sense, i.e. all its hom-sets are in fact sets.

Lemma 2.14. Let A^\bullet be any acyclic complex in $K^+(\mathcal{A})$ and I^\bullet a complex of injectives from $K^+(\mathcal{J})$. Then

$$\text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) = 0.$$

In other words every morphism from an acyclic complex to an injective one is nullhomotopic.

Proof. We will show that $f \simeq 0$ for any chain map $f: A^\bullet \rightarrow I^\bullet$ by inductively constructing an appropriate homotopy h . For simplicity assume $A^i = 0$ and $I^i = 0$ for $i < 0$ and define $h^i: A^i \rightarrow I^{i-1}$ to be 0 for $i \leq 0$.

maybe I replace "usual" with "locally small everywhere this comes up."

As A^\bullet is acyclic, the first non-trivial differential $d^0: A^0 \rightarrow A^1$ is mono. From I^0 being injective, we obtain a morphism $h^1: A^1 \rightarrow I^0$, satisfying

$$f^0 = h^1 \circ d^0.$$

Note that the above can actually be rewritten to $f^0 = h^1 d^0 + \delta^{-1} h^0$, as $h^0 = 0$.

For the induction step assume that we have already constructed $h^i: A^i \rightarrow I^{i-1}$, with $f^{i-1} = h^i d^{i-1} + \delta^{i-2} h^{i-1}$ for all $i \leq n$. We are aiming to construct $h^{n+1}: A^{n+1} \rightarrow I^n$, for which $f^n = h^{n+1} d^n + \delta^{n-1} h^n$ holds. First, expand the differential d^n into a composition of the canonical epimorphism $e: A^n \rightarrow \text{coker } d^{n-1}$, followed by $j: \text{coker } d^{n-1} \rightarrow A^{n+1}$ induced by the universal property of $\text{coker } d^{n-1}$ by the map $d^n: A^n \rightarrow A^{n+1}$. Morphism j is actually a monomorphism by acyclicity of A^\bullet , since we know that

$$0 = H^n(A^\bullet) \simeq \ker(j: \text{coker } d^{n-1} \rightarrow A^{n+1}).$$

Next, we see that by the universal property of $\text{coker } d^{n-1}$, morphism $f^n - \delta^{n-1} h^n: A^n \rightarrow I^n$ induces a morphism $g: \text{coker } d^{n-1} \rightarrow I^n$, because

$$\begin{aligned} (f^n - \delta^{n-1} h^n) d^{n-1} &= f^n d^{n-1} - \delta^{n-1} h^n d^{n-1} \\ &= f^n d^{n-1} + \delta^{n-1} \delta^{n-2} h^{n-1} - \delta^{n-1} f^{n-1} \\ &= 0. \end{aligned}$$

The second equality follows from the inductive hypothesis and the third one from f being a chain map and $\delta^{n-1}, \delta^{n-2}$ being differentials.

Lastly, for I^n is injective and j mono, there is a morphism $h^{n+1}: A^{n+1} \rightarrow I^n$, satisfying $h^{n+1} \circ j = g$, thus after precomposing both sides with e , we arrive at $h^{n+1} d^n = f^n - \delta^{n-1} h^n$, which can be rewritten as

$$f^n = h^{n+1} d^n + \delta^{n-1} h^n. \quad \square$$

Lemma 2.15. *Let A^\bullet and B^\bullet belong to $K^+(\mathcal{A})$ and $I^\bullet \in K^+(\mathcal{J})$. Let $f: B^\bullet \rightarrow A^\bullet$ be a quasi-isomorphism, then*

$$\text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) \xrightarrow{f^*} \text{Hom}_{K^+(\mathcal{A})}(B^\bullet, I^\bullet)$$

is an isomorphism of k -modules.

Proof. In $K^+(\mathcal{A})$ we have a distinguished triangle $B^\bullet \rightarrow A^\bullet \rightarrow C(f)^\bullet \rightarrow B[1]^\bullet$, which induces a long exact sequence (of k -modules)

$$\begin{aligned} \cdots \longrightarrow \text{Hom}_{K^+(\mathcal{A})}(C(f)[-1]^\bullet, I^\bullet) &\longrightarrow \\ \longrightarrow \text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) &\xrightarrow{f^*} \text{Hom}_{K^+(\mathcal{A})}(B^\bullet, I^\bullet) \longrightarrow \\ &\longrightarrow \text{Hom}_{K^+(\mathcal{A})}(C(f)^\bullet, I^\bullet) \longrightarrow \cdots \end{aligned}$$

The reason being $\text{Hom}_{K^+(\mathcal{A})}(-, I^\bullet)$ is a cohomological functor by example 1.20. As f is a quasi-isomorphism, the cone $C(f)^\bullet$ is acyclic along with all its shifts. Since I^\bullet is a complex of injectives, f^* is clearly an isomorphism by lemma 2.14. \square

Lemma 2.16. *Let A^\bullet belong to $K^+(\mathcal{A})$ and I^\bullet to $K^+(\mathcal{J})$. Then the morphism action*

$$\text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) \rightarrow \text{Hom}_{D^+(\mathcal{A})}(A^\bullet, I^\bullet) \quad (2.3)$$

of the localization functor Q is an isomorphism of k -modules.

Proof. We already know this is a k -module homomorphism, thus it is enough to show that it is bijective. This is accomplished by constructing its inverse. Let $\phi: A^\bullet \rightarrow I^\bullet$ be a morphism in $D^+(\mathcal{A})$ and let $A^\bullet \xleftarrow{s} B^\bullet \xrightarrow{f} I^\bullet$ be its left roof representative. The morphism s being a quasi-isomorphism implies that $s^*: \text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) \rightarrow \text{Hom}_{K^+(\mathcal{A})}(B^\bullet, I^\bullet)$ is bijective by lemma 2.15, so there is a unique morphism $g: A^\bullet \rightarrow I^\bullet$, such that $f = g \circ s$ in $K^+(\mathcal{A})$. The inverse to (2.3) is then defined by sending ϕ to g .

First let's argue why this map is well-defined i.e. independent of the choice of left roof representative for ϕ . We pick two left roof representatives $A^\bullet \xleftarrow{s_0} B_0^\bullet \xrightarrow{f_0} I^\bullet$ and $A^\bullet \xleftarrow{s_1} B_1^\bullet \xrightarrow{f_1} I^\bullet$ for ϕ and let g_0 and g_1 be such that $f_i = g_i \circ s_i$ for both i . As the roofs are equivalent there are quasi-isomorphisms $t_0: C^\bullet \rightarrow B_0^\bullet$ and $t_1: C^\bullet \rightarrow B_1^\bullet$, which fit into the following commutative diagram.

$$\begin{array}{ccccc}
 & & C^\bullet & & \\
 & \swarrow t_0 & & \searrow t_1 & \\
 & B_0^\bullet & & B_1^\bullet & \\
 \swarrow s_0 & & \searrow s_1 & & \swarrow f_1 \\
 A^\bullet & & & & I^\bullet
 \end{array}$$

(Note: The diagram shows a commutative diagram with C^\bullet at the top, B_0^\bullet and B_1^\bullet in the middle, and A^\bullet and I^\bullet at the bottom. Arrows are: $C^\bullet \xrightarrow{t_0} B_0^\bullet$, $C^\bullet \xrightarrow{t_1} B_1^\bullet$, $B_0^\bullet \xrightarrow{s_0} A^\bullet$, $B_1^\bullet \xrightarrow{s_1} A^\bullet$, $B_0^\bullet \xrightarrow{f_0} I^\bullet$, $B_1^\bullet \xrightarrow{f_1} I^\bullet$, and $A^\bullet \xrightarrow{g_0} I^\bullet$, $A^\bullet \xrightarrow{g_1} I^\bullet$.)

Therefore $g_0 s_0 t_0 = f_0 t_0 = f_1 t_1 = g_1 s_1 t_1 = g_1 s_0 t_0$. As $s_0 t_0$ is a quasi-isomorphism, we see that $g_0 = g_1$ by applying lemma 2.15.

Following the diagram below, it is clear why the constructed map is a right inverse to (2.3)

$$\begin{aligned}
 \text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) &\xrightarrow{Q} \text{Hom}_{D^+(\mathcal{A})}(A^\bullet, I^\bullet) \longrightarrow \text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) \\
 (g: A^\bullet \rightarrow I^\bullet) &\longmapsto \left[A^\bullet \xleftarrow{\text{id}_{A^\bullet}} A^\bullet \xrightarrow{g} I^\bullet \right] \longmapsto (g: A^\bullet \rightarrow I^\bullet).
 \end{aligned}$$

Lastly we see that it is also a left inverse by the following diagram

$$\begin{aligned}
 \text{Hom}_{D^+(\mathcal{A})}(A^\bullet, I^\bullet) &\longrightarrow \text{Hom}_{K^+(\mathcal{A})}(A^\bullet, I^\bullet) \xrightarrow{Q} \text{Hom}_{D^+(\mathcal{A})}(A^\bullet, I^\bullet) \\
 \left[A^\bullet \xleftarrow{s} B^\bullet \xrightarrow{f} I^\bullet \right] &\longmapsto (g: A^\bullet \rightarrow I^\bullet) \longmapsto \left[A^\bullet \xleftarrow{\text{id}_{A^\bullet}} A^\bullet \xrightarrow{g} I^\bullet \right]
 \end{aligned}$$

along with observing that $A^\bullet \xleftarrow{\text{id}_{A^\bullet}} A^\bullet \xrightarrow{g} I^\bullet$ and $A^\bullet \xleftarrow{s} B^\bullet \xrightarrow{f} I^\bullet$ are equivalent roofs. \square

Proof of theorem 2.12. As $K^+(\mathcal{J}) \rightarrow D^+(\mathcal{A})$ is a triangulated functor, we only need to show that it is fully faithful and essentially surjective. Let I^\bullet and J^\bullet be objects of $K^+(\mathcal{J})$. Then

$$\text{Hom}_{K^+(\mathcal{J})}(I^\bullet, J^\bullet) \xrightarrow{=} \text{Hom}_{K^+(\mathcal{A})}(I^\bullet, J^\bullet) \xrightarrow{(2.16)} \text{Hom}_{D^+(\mathcal{A})}(I^\bullet, J^\bullet)$$

is a bijection, showing fully faithfulness (the last map is a bijection by lemma 2.16). Essential surjectivity is clear from the existence of injective resolutions (cf. proposition 2.10) because quasi-isomorphisms now play the role of isomorphisms in $D^+(\mathcal{A})$. \square

add a little argument for why injective res. are unique up to htpy.

2.1.2 Subcategories of derived categories

We have already seen $D^+(\mathcal{A})$, $D^-(\mathcal{A})$ and $D^b(\mathcal{A})$ be defined as full triangulated subcategories of $D(\mathcal{A})$ on the class of certain bounded complexes taking values in \mathcal{A} .

2.2 Derived functors

F-adapted classes

3 Derived categories in geometry

3.1 Derived category of coherent sheaves

One of the main invariants of a scheme X over k is its category of coherent sheaves $\mathrm{coh}(X)$. One can think of this category as a slight extension of the category of locally free \mathcal{O}_X -modules of finite rank also known as k -vector bundles on X in the sense that $\mathrm{coh}(X)$ is abelian, where as the former very often is not. In this chapter we restrict ourself to noetherian schemes and our primary object of study will be the bounded derived category of coherent sheaves

$$\mathrm{D}^b(X) := \mathrm{D}^b(\mathrm{coh}(X)).$$

Proposition 3.1. *The category of quasi-coherent sheaves $\mathrm{qcoh}(X)$, of a noetherian scheme X , contains enough injectives.*

Proposition 3.2. *For a noetherian scheme X the inclusion $\mathrm{D}^b(X) \hookrightarrow \mathrm{D}^b(\mathrm{qcoh}(X))$ induces an equivalence of triangulated categories*

$$\mathrm{D}^b(X) \simeq \mathrm{D}_{\mathrm{coh}}^b(\mathrm{qcoh}(X)),$$

where $\mathrm{D}_{\mathrm{coh}}^b(\mathrm{qcoh}(X))$ is the full triangulated subcategory of $\mathrm{D}^b(\mathrm{qcoh}(X))$, spanned on bounded complexes of quasi-coherent sheaves on X with coherent cohomology.

Proposition 3.3.

Theorem 3.4. [Huy06, Proposition 3.10] *The bounded derived category $\mathrm{D}^b(X)$ of a connected noetherian scheme X is indecomposable.*

3.2 Derived functors in algebraic geometry

In this subsection we will derive some functors occurring in algebraic geometry and later state some important facts relating them with each other. To derive these functors we will either deal with injective sheaves and access the realm of quasi-coherent sheaves, following the first part of section ??, or introduce certain special classes of coherent sheaves depending on the functor we wish to derive and taking up the role of adapted classes, mirroring what was done in subsection ??.

3.2.1 Global sections functor

Arguably the most common functor in algebraic geometry is the global sections functor. Associated to a scheme X , the functor of *global sections*

$$\Gamma: \text{Mod}_{\mathcal{O}_X} \rightarrow \text{Mod}_k$$

assigns to each \mathcal{O}_X -module \mathcal{F} its module of global sections $\mathcal{F}(X) = \Gamma(X, \mathcal{F}) = H^0(X, \mathcal{F})$ and to a morphism of \mathcal{O}_X -modules $\alpha: \mathcal{F} \rightarrow \mathcal{G}$ a homomorphism $\alpha_X: \mathcal{F}(X) \rightarrow \mathcal{G}(X)$. By abuse of notation we use Γ to also denote the restrictions of the global sections functor to subcategories $\text{qcoh}(X)$ and $\text{coh}(X)$ of $\text{Mod}_{\mathcal{O}_X}$.

As is commonly known, Γ is a left exact functor, so our aim is to construct its right derived counterpart. Due to $\text{coh}(X)$ not having enough injectives, we resort to $\text{qcoh}(X)$, on which we may define

$$\mathbf{R}\Gamma: \text{D}^+(\text{qcoh}(X)) \rightarrow \text{D}^+(\text{Mod}_k),$$

according to ??. Precomposing the latter functor with the inclusion $\text{D}^+(\text{coh}(X)) \rightarrow \text{D}^+(\text{qcoh}(X))$ leaves us with the derived functor

$$\mathbf{R}\Gamma: \text{D}^+(\text{coh}(X)) \rightarrow \text{D}^+(\text{Mod}_k).$$

A Spectral sequences and how to use them

In this chapter we will first define cohomological spectral sequences and discuss their meaning through applications related with derived categories.

At first, when encountering spectral sequences, one might think of them as just book-keeping devices encoding a tremendous amount of data, but we will soon see how elegantly one can infer certain properties related to derived categorical claims exploiting the fact that they can naturally be encoded with spectral sequences. One of the most important spectral sequences, which is also very general within our scope of inspection, will be the Grothendieck spectral sequence relating the higher derived functors of two composable functors with the higher derived functors of their composition. Later on we will see that many useful and well-known spectral sequences occur as special cases of the Grothendieck spectral sequence. What follows was gathered mostly from [Huy06, Chapter 2, 2.1] and [GM02, Chapter III.7].

For the time being we fix an abelian category \mathcal{A} and start off with a definition.

Definition A.1. A (cohomological) spectral sequence in an abelian category \mathcal{A} consists of the following data on which we further impose two convergence conditions.

- *Sequence of pages.* A sequence of bi-graded objects $(E_r^{\bullet, \bullet})_{r \in \mathbf{Z}_{\geq 0}}$ equipped with differentials of bi-degree $(r, 1 - r)$. The r -th term of this sequence is called the r -th page and it consists of a lattice of objects $E_r^{p, q}$ of \mathcal{A} , for $p, q \in \mathbf{Z}$, and differentials

$$d_r^{p, q} : E_r^{p, q} \rightarrow E_r^{p+r, q-r+1},$$

satisfying

$$d_r^{p+r, q-r+1} \circ d_r^{p, q} = 0,$$

for each $p, q \in \mathbf{Z}$.

- *Isomorphisms.* A collection of isomorphisms

$$\alpha_r^{p, q} : H^{p, q}(E_r) \xrightarrow{\sim} E_{r+1}^{p, q},$$

for all $p, q \in \mathbf{Z}$ and $r \in \mathbf{Z}_{\geq 0}$, where

$$H^{p, q}(E_r) := \ker(d_r^{p, q}) / \operatorname{im}(d_r^{p-r, q+r-1}),$$

which allow us to turn the pages.

- *Transfinite page.* A bi-graded object $E_\infty^{\bullet, \bullet}$.
- *Goal of computation.* A sequence of objects $(E^n)_{n \in \mathbf{Z}}$ of the category \mathcal{A} .

The above collection of data also has to satisfy the following two convergence conditions.

1. For each pair (p, q) , there exists $r_0 \geq 0$, such that for all $r \geq r_0$ we have

$$d_r^{p, q} = 0 \quad \text{and} \quad d_r^{p+r, q-r+1} = 0$$

and the isomorphism $\alpha_r^{p, q}$ can be taken to be the identity. We then say that the (p, q) -term stabilizes after page r_0 and we denote $E_{r_0}^{p, q}$ (along with all the subsequent $E_r^{p, q}$ for $r \geq r_0$) by $E_\infty^{p, q}$.

2. For each $n \in \mathbf{Z}$ there is a decreasing *regular*⁸ filtration of E^n

$$E^n \supseteq \dots \supseteq F^p E^n \supseteq F^{p+1} E^n \supseteq \dots \supseteq 0$$

and isomorphisms

$$\beta^{p,q} : E_\infty^{p,q} \xrightarrow{\sim} F^p E^{p+q} / F^{p+1} E^{p+q}$$

for all $p, q \in \mathbf{Z}$.

In this case we also denote the existence of such a spectral sequence by

$$E_r^{p,q} \implies E^n.$$

Remark A.2. A few words are in order to justify us naming the sequence $(E^n)_{n \in \mathbf{Z}}$ our *goal of computation*. Usually one is given a starting page or a small number of them and the first goal is to identify the transfinite page – we are referring to convergence condition (a). Often one is able to infer the differentials degenerate after a number of turns of the pages from context or by observing the shape of the spectral sequence. For example *first quadrant spectral sequences*, i.e. the ones with non-trivial $E_r^{p,q}$ only for (p, q) lying in the first quadrant, always satisfy condition (a).

The second part of the computation is concerned with relating objects from the transfinite page $E_\infty^{\bullet,\bullet}$ with objects E^n . This is captured in the convergence condition (b), from which we can clearly observe that the intermediate quotients of the filtration $(F^p E^n)_{p \in \mathbf{Z}}$ for a fixed term E^n lie on the anti-diagonal of the transfinite page passing through e.g. $E_\infty^{n,0}$.

In condition (b) the existence of isomorphisms $\beta^{p,q}$ can also be restated by saying that $E_\infty^{p,q}$ fits into a short exact sequence

$$0 \rightarrow F^{p+1} E^n \rightarrow F^p E^n \rightarrow E_\infty^{p,q} \rightarrow 0.$$

This observation becomes very useful when considering properties of objects of the category \mathcal{A} which are closed under extensions, especially when the filtration of E^n is finite.

mention Tohoku paper

Theorem A.3 (Grothendieck). *Let $F: \mathcal{A} \rightarrow \mathcal{B}$ and $G: \mathcal{B} \rightarrow \mathcal{C}$ be left exact functors between abelian categories. Let \mathcal{I}_F be an F -adapted class in \mathcal{A} , \mathcal{I}_G a G -adapted class of objects in \mathcal{B} and suppose every object of \mathcal{I}_F is sent to a G -acyclic object by the functor F . Then for every A^\bullet in $K^+(\mathcal{A})$ there exists a spectral sequence*

$$E_2^{p,q} = \mathbf{R}^p G(\mathbf{R}^q F(A^\bullet)) \implies \mathbf{R}^{p+q}(G \circ F)(A^\bullet).$$

B Lattice theory

⁸In our case the filtration $(F^p E^n)_{p \in \mathbf{Z}}$ is *regular*, whenever $\bigcap_p F^p E^n = \lim_p F^p E^n = 0$ and $\bigcup_p F^p E^n = \text{colim}_p F^p E^n = E^n$.

Zelo pomembno vlogo v algebraini geometriji igra kohomologija geometrijskega objekta, kot je shema ali raznoterost, X glede na, denimo, koherentni snop \mathcal{F} na X . Eden izmed načinov računanja kohomoloških grup $H^i(X, \mathcal{F})$, ki ga bomo tudi spoznali v poglavju ??, vključuje sledeče. Namesto, da intrinzično obravnavamo snop \mathcal{F} , ga predstavimo s t. i. *resolucijo* ali *predstavitvijo*, ki jo sestavljata kompleks snopov F^\bullet , členi katerega pripadajo nekemu razredu snopov, ki ima glede na kohomologijo določene ugodne lastnosti, in kvazi-izomorfizem $F^\bullet \rightarrow \mathcal{F}$ ali $\mathcal{F} \rightarrow F^\bullet$. Ker spememba resolucije na kohomologijo ne bo imela vpliva in ker lahko vsak snop zase vidimo tudi kot kompleks zgoščen v stopnji 0, želimo snop \mathcal{F} obravnavati enako kot vse njegove resolucije. Pogledano od daleč, želimo homotopsko kategorijo $K(\text{coh}(X))$ spremeniti tako, da se snop \mathcal{F} identificira z vsemi svojimi resolucijami, oz. z drugimi besedami, želimo vse kvazi-izomorfizme v $K(\text{coh}(X))$ spremeniti v izomorfizme. Slednje bo naše vodilo, da za splošno abelovo kategorijo \mathcal{A} vpeljemo njej prirejeno izpeljano kategorijo $D(\mathcal{A})$.

morda intrinzično ni prava beseda, ker so klasično predstavitve zajele ravno informacijo o generatorjih, relacijah,...
